In most of the studies, ST elevation in V1 or V2 was seen in most of the cases. In our case, lateral V1 was involved. Several studies have reported the presence of a major conduit artery stenosis in the infarct zone with a focus on the posterior descending artery. The stenotic lesions in the posterior descending artery are more likely to occur due to the anatomic relationship with a low distal LAD and also because the stenotic lesion may be less likely to be amenable to percutaneous intervention as compared to the proximal LAD \[[@B13]\]. However, some studies have shown that not all of the LAD is non-dominant in patients with AMI and all of the diseased arterial segments are not necessarily non-dominant.\[[@B14],[@B15]\] In our case, we have demonstrated that the proximal LAD is also at risk for developing ischemia if the distal LAD is not dominant and is the only inflow conduit. The non-dominant LAD territory is sometimes referred to as a "dominant LAD" and these patients may be at risk for an inferior wall infarction if they fail to receive reperfusion therapy.
